

<p><b>Class Notes</b> <i>Cellular Respiration</i></p> <p><b>Questions/Main Idea:</b></p>	<p>Name: _____ Period: _____ Date: _____</p> <p style="text-align: center;"><b>Notes:</b></p>
Cellular Respiration	<input type="checkbox"/> ...Using glucose to make energy (ATP).
Where Do Plants Get Energy?	<input type="checkbox"/> Plants get energy from the sun and store it in the bonds of glucose
Glucose Turns into Energy	<ul style="list-style-type: none"> <li>• How do we get energy?             <ul style="list-style-type: none"> <li>– by eating food.</li> </ul> </li> <li>• What types of food provide the most energy?             <ul style="list-style-type: none"> <li>– Carbs (sugars or glucose) have the most energy</li> </ul> </li> <li>• What does your body do to the food you eat?             <ul style="list-style-type: none"> <li>– digests our food (breaks apart bonds), releasing energy</li> </ul> </li> </ul>
Breaking Bonds	<input type="checkbox"/> Breaking bonds releases energy! <ul style="list-style-type: none"> <li>▪ Energy is “stored” in the glucose bonds; breaking them releases the energy</li> </ul> <input type="checkbox"/> What form of energy do our cell (and our body) use? <ul style="list-style-type: none"> <li>▪ the molecule ATP</li> </ul> <input type="checkbox"/> <i>So.. our body breaks down glucose and uses it to make ATP (ENERGY!)</i> <input type="checkbox"/> Which <b>organelle</b> is responsible for producing energy for our cells? <ul style="list-style-type: none"> <li>▪ The MITOCHONDRIA</li> </ul>
What is ATP?	<input type="checkbox"/> ATP (adenosine triphosphate) is a nucleic acid that can transfer energy within the cell. <input type="checkbox"/> Ex: a small amount of energy from a glucose molecule can be used directly... <input type="checkbox"/> The extra energy is transferred to ATP. <input type="checkbox"/> The energy in ATP is stored in the bonds between the phosphates (ATP has 3 phosphates).
Steps of Cellular Respiration  Step 1: Glycolysis	<input type="checkbox"/> glyco = refers to glucose <input type="checkbox"/> lysis = break apart <input type="checkbox"/> Glycolysis = break down 1 <b>glucose</b> into 2 <b>pyruvic acid</b> molecules, which have three carbons each (splits glucose in half) <input type="checkbox"/> Also makes <b>2 ATP!</b> 😊 <input type="checkbox"/> Takes place in the <b>cytoplasm</b>
Why Glycolysis?	<input type="checkbox"/> Glucose molecules are too large to move into the mitochondria, so glycolysis makes them smaller to get through the mitochondria’s membranes
Possible paths in respiration...  	<input type="checkbox"/> After glycolysis, there are two possible paths: <input type="checkbox"/> Aerobic respiration – requires oxygen <input type="checkbox"/> <b>Anaerobic</b> respiration – does not require oxygen; happens if oxygen is <b>lacking</b>

Aerobic Respiration	<ul style="list-style-type: none"> <li>☐ An <b>aerobic</b> process (requires oxygen).</li> <li>☐ Takes place in the mitochondria.</li> <li>☐ Equation:  <math display="block">6\text{O}_2 + \text{C}_6\text{H}_{12}\text{O}_6 \rightarrow 6\text{H}_2\text{O} + 6\text{CO}_2 + 36\text{ATP}</math>           Oxygen + Glucose                  Water + Carbon Dioxide + Energy         </li> </ul>
HOLD IT! Notice Anything Similar?	Equation for photosynthesis: $\text{Energy} + 6\text{H}_2\text{O} + 6\text{CO}_2 \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$ Equation for aerobic cellular respiration: $6\text{O}_2 + \text{C}_6\text{H}_{12}\text{O}_6 \rightarrow 6\text{H}_2\text{O} + 6\text{CO}_2 + 36\text{ATP}$
Organisms that Do Aerobic Cellular Respiration	<ul style="list-style-type: none"> <li style="width: 50%;">☐ Plants</li> <li style="width: 50%;">☐ Protists</li> <li style="width: 50%;">☐ Animals</li> <li style="width: 50%;">☐ Some bacteria</li> <li style="width: 50%;">☐ Fungi</li> <li style="width: 50%;">☐ ...almost everything alive!</li> </ul>
Aerobic Cellular Respiration	<ul style="list-style-type: none"> <li>☐ Recap: Step 1 = glycolysis -- 2 ATPs produced in cytoplasm and enter mitochondria.</li> <li>☐ For aerobic respiration, in mitochondria:           <ul style="list-style-type: none"> <li>▪ Step 2 = Krebs Cycle (Citric Acid Cycle) – in matrix</li> <li>▪ Step 3 = Electron Transport Chain – in inner membrane</li> </ul> </li> <li>☐ ATP is generated in each step, but most of the ATP is made in the Electron Transport Chain</li> </ul>
Krebs Cycle and ETC	See separate handouts
Anaerobic Cellular Respiration	<ul style="list-style-type: none"> <li>☐ AKA: <b>fermentation</b></li> <li>☐ Two types:           <ul style="list-style-type: none"> <li>▪ Alcohol fermentation</li> <li>▪ Lactic acid fermentation</li> </ul> </li> <li>☐ Both take place in the cytoplasm.</li> <li>☐ Each creates 2 ATP from each pyruvic acid molecule.</li> </ul>
Alcohol Fermentation	<ul style="list-style-type: none"> <li>☐ Yeast can do aerobic or anaerobic respiration.</li> <li>☐ Grapes turn to alcohol by adding yeast in containers with out oxygen.</li> <li>☐ Bread rises because yeast gives off CO<sub>2</sub> bubbles while fermenting in dough.</li> </ul>
Lactic Acid Fermentation	<ul style="list-style-type: none"> <li>☐ When humans (and other animals) exercise intensely, their muscles often use more O<sub>2</sub> than is available</li> <li>☐ When O<sub>2</sub> runs out, muscles switch to anaerobic respiration to try to keep up with energy demand.</li> <li>☐ This is lactic acid fermentation.</li> <li>☐ The build up of lactic acid is what makes your muscles sore.</li> </ul>
Aerobic v. Anaerobic Respiration	<ul style="list-style-type: none"> <li>☐ You get <b>way</b> more ATP from aerobic cellular respiration than from fermentation.</li> <li>☐ Fermentation is mostly used to provide organisms with short-term bursts of energy when oxygen is not available.</li> </ul>
<b>Summary:</b>
